Outline

- What is the BC Healthy Connections Project?
- Our progress to date
 - Participant characteristics upon trial entry
 - Retention protocol
 - Prenatal substance use findings
- Next steps and implications
- Acknowledgements
- Discussion

What is the BC Healthy Connections Project?

BC Healthy Connections Project

- Canadian randomized controlled trial evaluating Nurse-Family Partnership (NFP) (2011–2022)
- 739 young mothers and 737 children across British Columbia (BC)

Why a Canadian NFP Evaluation?

- Differing findings across US, Netherlands and England trials
- Need to evaluate NFP in Canada before widespread implementation
 - Outcomes may differ across contexts
 - Differing existing health and social services

Why a Canadian NFP Evaluation?

- ❑ Adapt NFP and test its local feasibility and acceptability
 - ✓ Successful McMaster-Hamilton pilot using Canadian curriculum, led by Susan Jack and Harriet MacMillan (2008)

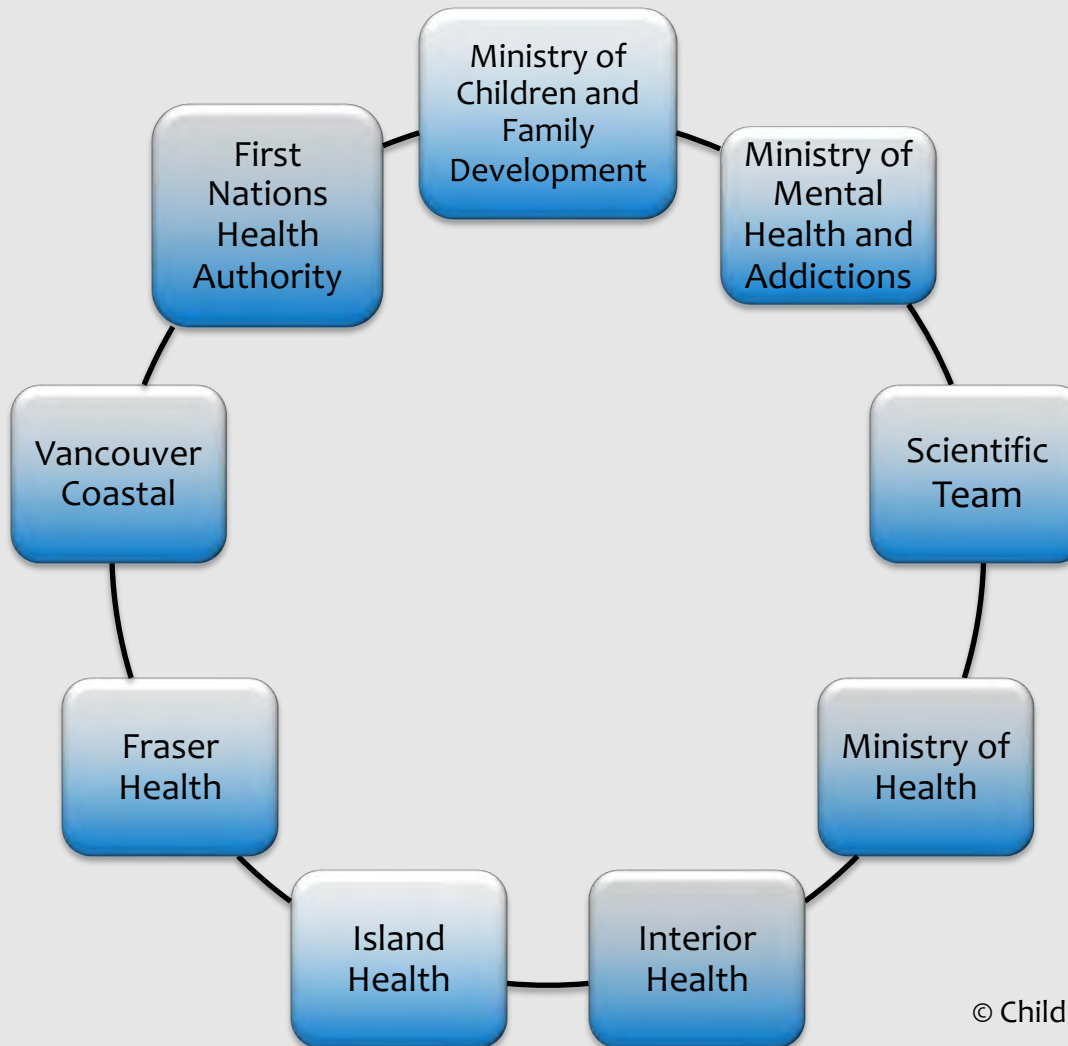

Why a Canadian NFP Evaluation?

- ❑ Adapt NFP and test its local feasibility and acceptability
 - ✓ Successful McMaster-Hamilton pilot using Canadian curriculum, led by Susan Jack and Harriet MacMillan (2008)
- ❑ Evaluate NFP in a large-scale randomized controlled trial
 - ✓ **BC Healthy Connections Project**

BC Healthy Connections Project

- Trial launched (2011-2022)
- Embedded within BC's public and child health systems
- Reciprocal and sustained research-policy-practice collaborations

Research-Policy-Practice Collaborations

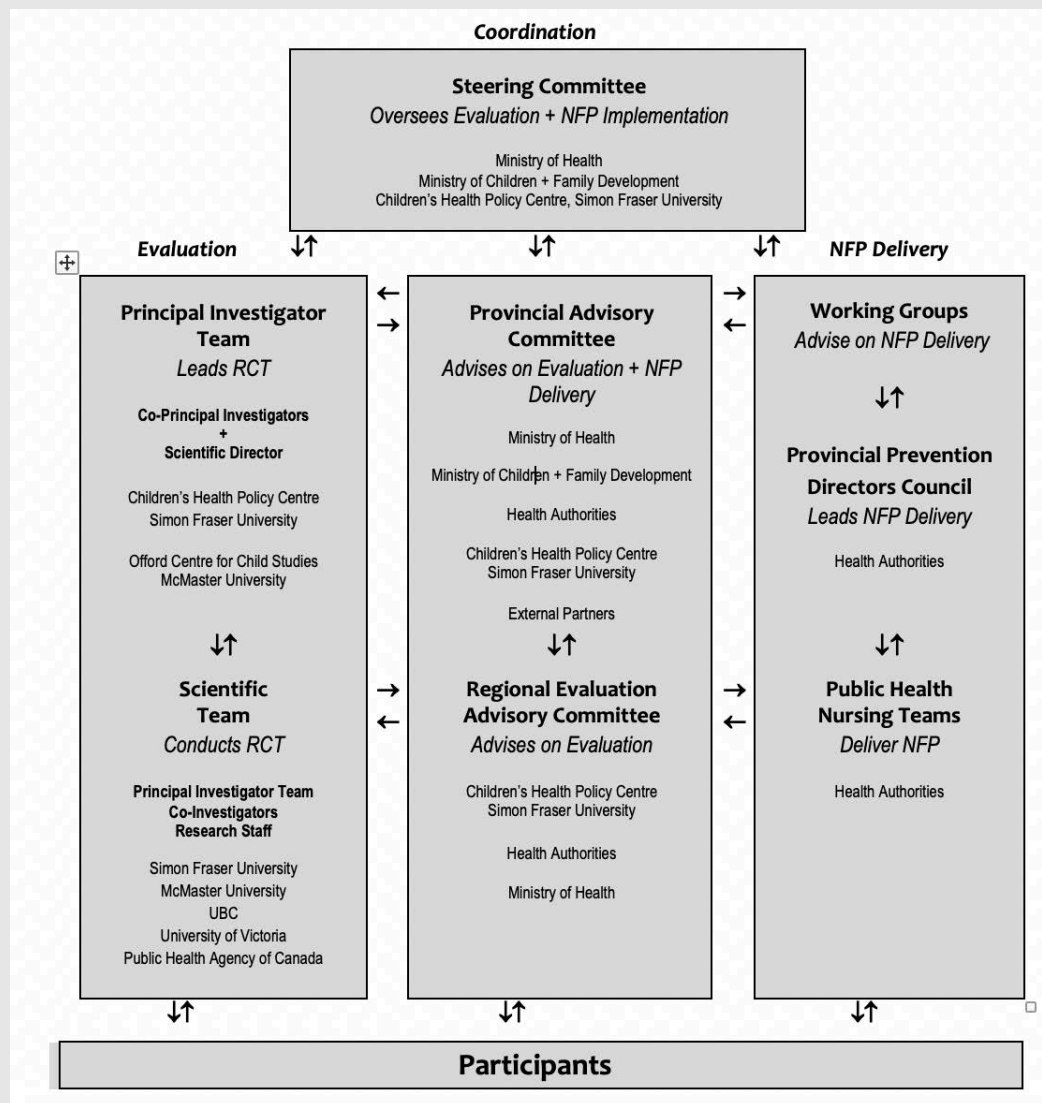

- Simon Fraser University
- McMaster University
- University of British Columbia
- University of Victoria
- Public Health Agency of Canada

BC Healthy Connections Project

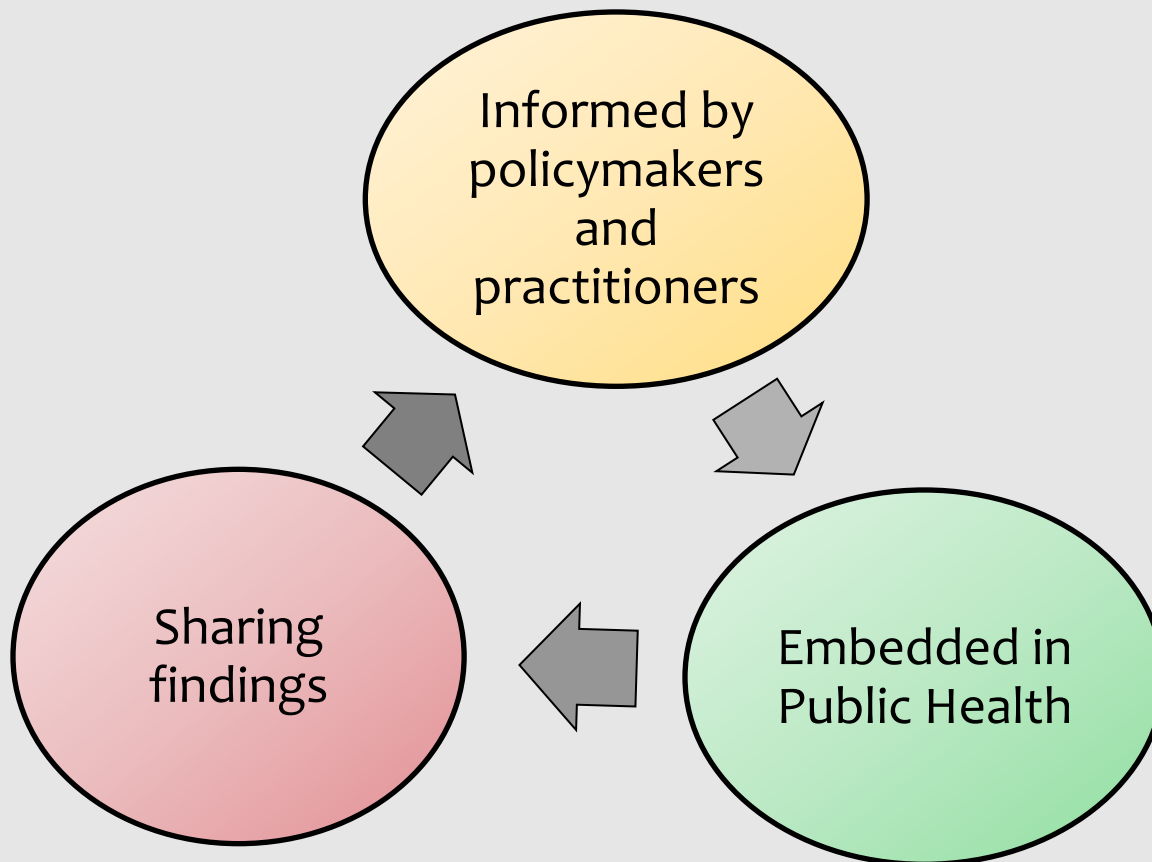

- Governance structure guides our work

BC Healthy Connections Project

Eligibility Criteria

Inclusion: Eligible if all criteria met at time of baseline interview

1. Aged 24 years or younger
2. Preparing to parent for the first time
3. Less than 28 weeks gestation
4. Able to provide informed consent including conversational competence in English
5. Experiencing socioeconomic disadvantage

Exclusion: Ineligible if any criteria met at time of baseline interview

1. Planning to have the child adopted
2. Planning to leave catchment area for three months or longer

(Table adapted from Catherine, Gonzalez, Boyle et al., 2016)

Eligibility Criteria

Socioeconomic disadvantage criteria

- Age 19 years or younger
- Age 20–24 years and met 2 of 3 indicators
 - Being single
 - Having low education
 - Having limited income defined as:
 - Receiving income assistance
 - Finding it difficult to live on total income regarding food or rent
 - Experiencing homelessness

Eligibility Criteria

Participants living in First Nations communities

- Developed in consultation with First Nations leaders and respecting the study's research ethics approvals
 - Eligible if living “off reserve” at time of baseline interview
 - Requesting permission from the Chief of the local First Nation if a participant moved to the community and wished to continue in the study
 - Every request to a Chief was approved

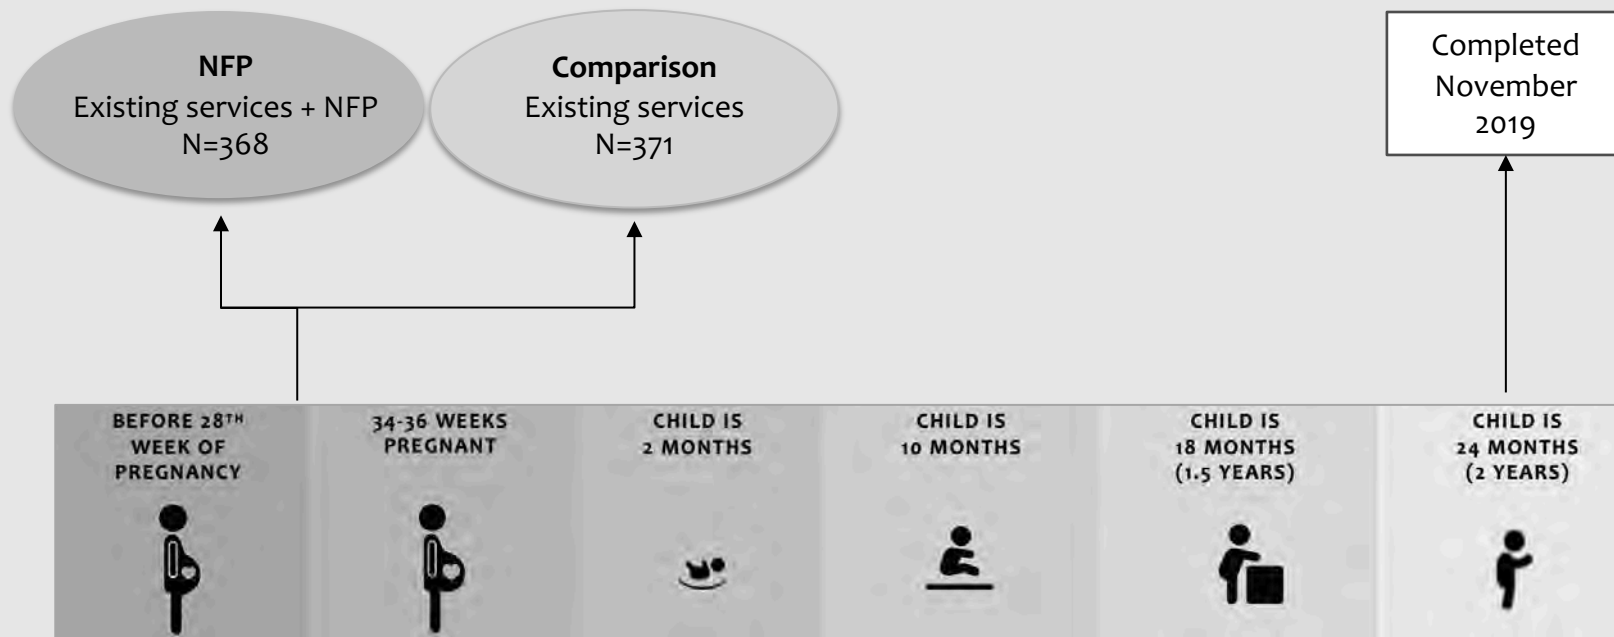

Main Outcome Indicators

Domain	Primary Indicator	Secondary Indicators
Pregnancy		Prenatal tobacco and alcohol use <ul style="list-style-type: none"> • <i>Maternal Self-Report</i>
Child Health	Childhood injuries (birth → 2 years) <i>Ministry of Health data on community/outpatient, emergency and hospital healthcare encounters</i>	Child cognitive and language development at age 2 years <ul style="list-style-type: none"> • <i>Bayley Scales of Infant and Toddler Development III</i> • <i>MacArthur-Bates Communicative Development Inventories: Words and Sentences</i> Child mental health at age 2 years <ul style="list-style-type: none"> • <i>Child Behavior Check List</i>
Maternal Health		Subsequent pregnancies (2 years postpartum) <ul style="list-style-type: none"> • <i>Maternal Self-Report</i>

Other Outcome Indicators

- Child
 - Physical health and wellness
- Maternal
 - Mental health, self-efficacy, parenting, exposure to violence
- Family
 - Income, social supports, housing, service use

Improving children's health and development in British Columbia through nurse home visiting: a randomized controlled trial protocol

Nicole L. A. Catherine^{1*}, Andrea Gonzalez^{2,3}, Michael Boyle^{2,3}, Debbie Sheehan^{1,2}, Susan M. Jack^{2,4}, Kaitlyn A. Hougham¹, Lawrence McCandless⁵, Harriet L. MacMillan^{2,3}, Charlotte Waddell¹ and For the British Columbia Healthy Connections Project Scientific Team

Abstract

Background: Nurse-Family Partnership is a nurse home visitation program that aims to improve the lives of young mothers and their children. The program focuses on women who are parenting for the first time and experiencing socioeconomic disadvantage. Nurse visits start as early in pregnancy as possible and continue until the child reaches age two years. The program has proven effective in the United States – improving children's mental health and development and maternal wellbeing, and showing long-term cost-effectiveness. But it is not known whether the same benefits will be obtained in Canada, where public services differ. The British Columbia Healthy Connections Project therefore involves a randomized controlled trial evaluating Nurse-Family Partnership's effectiveness compared with existing (usual) services in improving children's mental health and early development and mother's life circumstances. The trial's main aims are to: reduce childhood injuries by age two years (primary outcome indicator); reduce prenatal nicotine and alcohol use; improve child cognitive and language development and behaviour at age two years; and reduce subsequent pregnancies by 24 months postpartum. Potential explanatory factors such as maternal mental health (including self-efficacy) are also being assessed, as is the program's impact on exposure to intimate-partner violence. To inform future economic evaluation, data are also being collected on health and social service access and use.

Methods/design: Eligible and consenting participants (N = 1040) are being recruited prior to 28 weeks gestation then individually randomized to receive existing services (comparison group) or Nurse-Family Partnership plus existing services (intervention group). Nurse-Family Partnership is being delivered following fidelity guidelines. Data are being collected during in-person and telephone interviews at baseline; 34–36 weeks gestation; and two, 10, 18 and 24 months postpartum. Additional data will be obtained via linkages from provincial datasets. Recruitment commenced in October 2013 and will continue for approximately three years.

Discussion: This trial will provide important information about the generalizability of Nurse-Family Partnership to the Canadian context. Findings will be published in peer-reviewed journals and shared with policymakers and practitioners through extensive public health collaborations already underway.

Trial registration: Registered July 18, 2013 with ClinicalTrials.gov Identifier: NCT01672060.

Keywords: Nurse-family partnership, Randomized controlled trial, Early child development, Prevention, Child injuries

Adjunctive Studies

- NFP Process Evaluation
 - Qualitative interviews and focus groups with NFP nurses and program managers
 - Informing BC-specific program improvements
 - Led by Susan Jack, funded by Public Health Agency of Canada
- Biological Evaluation
 - Biomarkers from 380 children and mothers
 - Led by Andrea Gonzalez, funded by Canadian Institutes of Health Research

Progress to Date

- I. Participant characteristics upon trial entry
- II. Retention protocol
- III. Prenatal substance use findings

Participant Characteristics upon Trial Entry

Participant Characteristics upon Trial Entry

Baseline Data

- Describing our 739 participants when they first entered the study in early pregnancy
 - Before random group allocation
 - A robust sample size, yet this represents only a small proportion ($\ll 50\%$) of eligible participants across BC
- Many measures depict risks, as a stepping stone to understanding needs and addressing them

Cultural Background

- 27% Indigenous
- 57% “White”
- Other categories included mixed heritage, Filipina, Latin-American, South Asian, “Black” and Chinese

The sample does not fully reflect BC's diversity, likely due to eligibility criteria requiring English-language competence, yet Indigenous girls and young women are over-represented.

Indicators of Socioeconomic Disadvantage

- 49% between 14–19 years
- 91% Single
- 52% Having limited education
- 84% Having low income

Health and Social Adversities

Adversities	N = 739
Unstable Housing	52%
Psychological Distress	32%
Anxiety or Depression	47%
Prenatal Substance Use	24%
Cannabis	21%
Cigarettes	27%
Alcohol	2%
Street drugs	1.5%
Physical Health Challenges	20%
History of Childhood Maltreatment	56%
Intimate Partner Violence recently	51%

(Table adapted from Catherine, Lever, Sheehan et al., 2019)

Receiving Services, or Not?

	Percentage
Health Services (past month)	
Primary Health Care	77%
Prenatal Classes	28%
Social Services (past month)	
BC Income Assistance	29%
BC Medical Services Plan Assistance	35%

(Table adapted from Catherine, Lever, Sheehan et al., 2019)

Coping with Multiple Adversities

- Indicators based on trial eligibility criteria and BC public health prenatal registry screening criteria
 - Young age; low income; limited education; exposure to maltreatment as a child; housing instability; mental health challenges with anxiety or depression and/or substance use; and/or intimate partner violence

Participants Affected	Indicators of Adversities
100%	1
98%	2
90%	3
76%	4
52%	5
34%	6
13%	7
5%	8

(Table adapted from Catherine, Lever, Sheehan et al., 2019)

Interpretations

- Our data show unacceptable rates of socioeconomic disadvantage for BC girls and young women who are preparing to parent for the first time
- BC Health Authorities have reached the population NFP was designed to benefit
 - But with only < 50% of possible population enrolled, many more need to be reached

Interpretations

- Most forms of disadvantage we have depicted are preventable
 - In addition to NFP, more adequate programs and services are needed to ensure that all young British Columbians are flourishing on an equal footing, starting early in life

The British Columbia Healthy Connections Project: findings on socioeconomic disadvantage in early pregnancy

Nicole L. A. Catherine^{1*}, Rosemary Lever¹, Debbie Sheehan¹, Yufei Zheng¹, Michael H. Boyle², Lawrence McCandless³, Amiram Gafni⁴, Andrea Gonzalez², Susan M. Jack⁵, Lil Tonmyr⁶, Colleen Varcos⁷, Harriet L. MacMillan⁸, Charlotte Waddell¹ and For the British Columbia Healthy Connections Project Scientific Team

Abstract

Background: Maternal exposure to socioeconomic disadvantage increases the risk of child injuries and subsequent child developmental and mental health problems — particularly for young mothers. To inform early intervention planning, this research therefore aimed to describe the health and social adversities experienced by a cohort of girls and young women in early pregnancy in British Columbia (BC), Canada.

Methods: Participants were recruited for the BC Healthy Connections Project (BCHCP), a randomized controlled trial examining the effectiveness of Nurse-Family Partnership, a home visitation program, in improving child and maternal outcomes. Baseline data were collected from 739 participants on trial entry. Participants were selected on the basis of preparing to parent for the first time and experiencing socioeconomic disadvantage. Analyses involved descriptive statistics and age-group comparisons.

Results: Most participants reported having low income (84%), having limited education (52%) and being single (91%) at trial entry. Beyond these eligibility criteria, other health and social adversities included: housing instability (52%); severe anxiety or depression (47%); other diagnosed mental disorders (22%); prenatal nicotine and cannabis use (27 and 21%); physical health problems (20%); child maltreatment when younger (56%); and intimate partner violence recently (50%). As well, few (29%) had received income assistance entitlements. More than two thirds (70%) were experiencing four or more forms of adversity. Age-group differences were observed for cognitive functioning, being single, low income, limited education, psychological distress and service use (p -value ≤ 0.05).

Conclusions: This cohort was selected on the basis of socioeconomic disadvantage. Yet all participants were experiencing substantial added adversities — at higher rates than other Canadians. Furthermore, despite Canada's public programs, these pregnant girls and young women were not being adequately reached by social services. Our study adds new data to inform early intervention planning, suggesting that unacceptably high levels of socioeconomic disadvantage exist for some young British Columbians. Therefore greater health and social supports and services are warranted for these young mothers and their children.

Trial registration: Registered August 24, 2012 with ClinicalTrials.gov Identifier: NCT01672060. Active not recruiting.

Keywords: Pregnancy, Adolescents, Maternal health, Socioeconomic disadvantage, Cumulative disadvantage

Indigenous Participants

Indigenous Participants

- Collaborating with the BC First Nations Health Authority
- Baseline data on the 200 Indigenous participants
- Self-identified as Indigenous (First Nations, Aboriginal, Indigenous, Métis or Inuit)

Indigenous Participants

- Findings were framed to showcase strengths
 - High representation of Indigenous participants: 27% versus 6% in the population despite no specialized referral pathways
 - Seeking support during pregnancy

Indigenous Participants

- Findings were framed to showcase strengths
 - High representation of Indigenous participants: 27% versus 6% in the population despite no specialized referral pathways
 - Seeking support during pregnancy
 - Participating in research as contributing to the common good
 - Long-term research study (2.5 years) involving their first child
 - Possibility of frequent nurse-home visits

Indigenous Participants

- Findings were framed to showcase strengths
 - 75% sought out primary healthcare
 - 38% attended prenatal classes
 - 34% were receiving income assistance

Indigenous Participants

- Most were experiencing adversities associated with legacies of colonialism
 - This did not deter participants from seeking prenatal care

Indigenous Participants

Indicators of socioeconomic disadvantage

- 91% Single
- 67% Having limited education
- 93% Having low income

Indigenous Participants

Adversities	N = 200
Unstable Housing	63%
Psychological Distress	29%
Anxiety or Depression	49%
Prenatal Substance Use	50%
Cannabis	31%
Cigarettes	29%
Alcohol	8%
Street drugs	1.5%
Physical Health Challenges	23%
History of Childhood Maltreatment	59%
Intimate Partner Violence recently	51%

(Manuscript in preparation)

Interpretations

- These are new BC data on Indigenous families
- Need for investments in culturally-appropriate interventions that address social determinants of health
 - Support child health and well-being

Interpretations

- Advocating for Indigenous mothers and their children
- Defying negative stereotypes

Research-Policy Collaboration

- In collaboration with BC First Nations Health Authority co-authors
 - Manuscript submission to *International Indigenous Policy Journal*

Retention Protocol

Retention Protocol

- BCHCP = Case example for developing planned theory- and evidence-informed retention protocol

Retention Protocol

- Attrition presents serious threats to validity of trial results
 - Participant retention is crucial and requires adequate planning and resources
- Challenges are magnified for populations experiencing disadvantage
- Researchers often fail to identify and address barriers to participation
 - Labelling as “hard-to-reach”

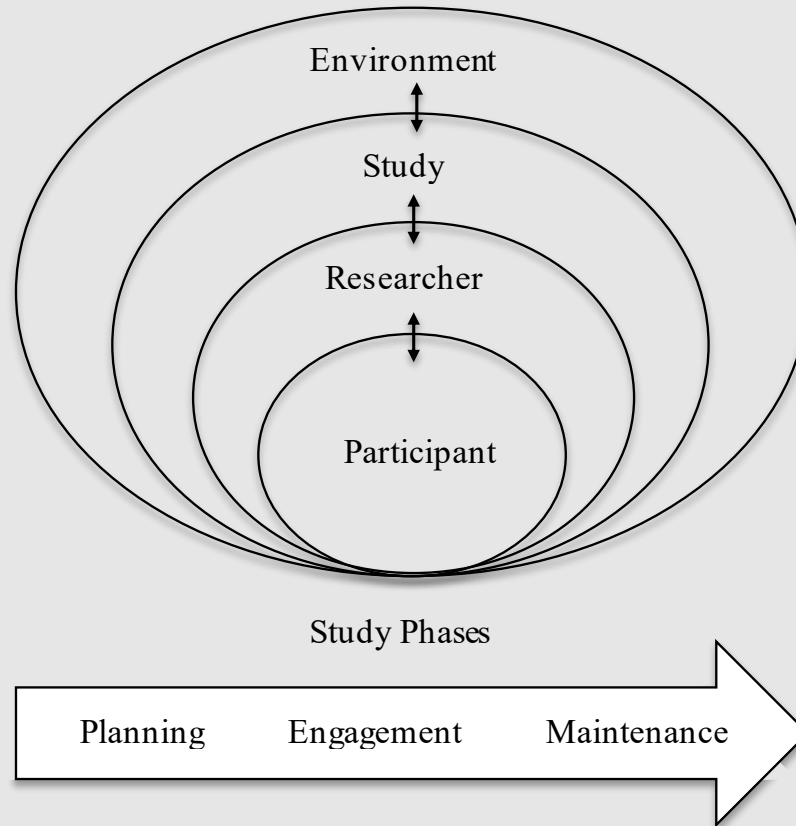

Retention Protocol

- Systematic reporting of planned, theory-informed retention strategies is lacking in long-term health research
- In contrast to standardized protocols required for registering and reporting
 - RCTs = CONSORT
 - Systematic reviews = PRISMA, PROSPERO

Retention Protocol

1. Literature review
2. Ecological model of research participation
3. BCHCP Retention Framework
4. Barriers
5. Strategies
6. Recommendations to guide health researchers

“Why Did You Participate?”

“I appreciate that the workers never gave up in having me involved.”

Retention Protocol

Recommendations:

- Standardized retention protocols should be encouraged in research to promote consistency across diverse studies
- Improved retention planning may inform a shift for researchers, policymakers and practitioners from viewing disadvantaged populations as “hard-to-reach” to viewing them as “need-to-reach”

Implications

- Informing retention in programs and services
- Reaching all children to reduce disparities
 - Disproportionately affected by global disasters

Retaining participants in community-based health research: a case example on standardized planning and reporting

Nicole L. A. Catherine^{1*}, Rosemary Lever¹, Lenora Marcellus², Corinne Tallon³, Debbie Sheehan^{1,4}, Harriet MacMillan⁵, Andrea Gonzalez⁴, Susan M. Jack^{4,5} and Charlotte Waddell¹

Abstract

Background: Effective strategies for participant retention are critical in health research to ensure validity, generalizability and efficient use of resources. Yet standardized guidelines for planning and reporting on retention efforts have been lacking. As with randomized controlled trial (RCT) and systematic review (SR) protocols, *retention protocols* are an opportunity to improve transparency and rigor. An RCT being conducted in British Columbia (BC), Canada provides a case example for developing a priori retention frameworks for use in protocol planning and reporting.

Methods: The BC Healthy Connections Project RCT is examining the effectiveness of a nurse home-visiting program in improving child and maternal outcomes compared with existing services. Participants (N = 739) were girls and young women preparing to parent for the first time and experiencing socioeconomic disadvantage. Quantitative data were collected upon trial entry during pregnancy and during five follow-up interviews until participants' children reached age 2 years. A framework was developed to guide retention of this study population throughout the RCT. We reviewed relevant literature and mapped essential retention activities across the study planning, recruitment and maintenance phases. Interview completion rates were tracked.

Results: Results from 3302 follow-up interviews (in-person/telephone) conducted over 4 years indicate high completion rates: 90% (n = 667) at 34 weeks gestation; and 91% (n = 676), 85% (n = 626), 80% (n = 594) and 83% (n = 613) at 2, 10, 18 and 24 months postpartum, respectively. Almost all participants (99%, n = 732) provided ongoing consent to access administrative health data. These results provide preliminary data on the success of the framework.

Conclusions: Our retention results are encouraging given that participants were experiencing considerable socioeconomic disadvantage. Standardized retention planning and reporting may therefore be feasible for health research in general, using the framework we have developed. Use of standardized retention protocols should be encouraged in research to promote consistency across diverse studies, as now happens with RCT and SR protocols. Beyond this, successful retention approaches may help inform health policy-makers and practitioners who also need to better reach, engage and retain underserved populations.

Reducing Prenatal Substance Use

Cost of Substance Use in Canada

A large, light orange oval shape centered on the page, containing the text '\$40 billion/year' in black font.

\$40 billion/year

Main Outcome Indicators

Domain	Primary Indicator	Secondary Indicators
Pregnancy		Prenatal tobacco and alcohol use (cannabis and street drugs)
Child Health Age 2	Childhood injuries	Child cognitive and language development Child mental health
Maternal Health		Subsequent pregnancies

Prenatal Analyses

- Analyses were by intention-to-treat (90% retention)
- Examined change in substance use from baseline to 34-36 weeks
 - Difference in before-after changes

Reductions by Late Pregnancy

Substance	Baseline (<28 weeks)		Change by week 34-36	
	NFP	Existing Services	NFP	Existing Services
Cigarette (past two days)	25.4%	27.8%	↓ 5.8%	↓ 2.5%
Alcohol (past month)	6.3%	5.1%	↓ 2.6%	↓ 1.9%
Cigarette Count, Smoker (past two days)	8.4	6.8	↓ 2.5*	↓ 0.8
Cannabis (past month)	25.3%	25.9%	↓ 8.5%*	↓ 4.7%
Street Drugs (past month)	2.5%	1.1%	↓ 2.5%	↓ 0.5%

(Table adapted from Catherine, Boyle, Zheng et al., 2020)

Interpretations | Cigarettes

- For smokers, NFP resulted in modest yet significant decreases in cigarettes
 - Any reductions may benefit the developing fetus as low levels are shown to be harmful

Interpretations | Cannabis

- NFP also reduced prenatal cannabis use, an emerging public health problem
- Increasing prenatal use in Canada, especially in those experiencing disadvantage
 - Adversely impacts fetus and child cognitive and behavioural development
 - Potency is increasing
 - Public perceptions: harmless or even beneficial in pregnancy

Interpretations | Cannabis

- Harm reduction efforts need to be intensified
- NFP may have a role in these efforts, particularly for disadvantaged populations

Interpretations | Alcohol and Street Drugs

- No evidence of benefit
 - Too infrequent, public health efforts may have been successful for alcohol

Integrated Knowledge Translation

- Active, reciprocal engagement throughout the research process
 - Provincial Advisory Committee
 - Ensuring findings are relevant to knowledge users, including policymakers
- One-page scientific update
 - Informed by BCHCP Steering Committee
 - Local, national and international audience

Implications

- In British Columbia, NFP may reduce harms for BCHCP children starting prenatally
- Major cost-savings associated with addressing avoidable adversities and reducing prenatal substance use
- More still needs to be done
 - High rates of baseline socioeconomic disadvantage
 - High rates of baseline prenatal cigarette and cannabis use (26%)

Nurse home visiting and prenatal substance use in a socioeconomically disadvantaged population in British Columbia: analysis of prenatal secondary outcomes in an ongoing randomized controlled trial

Nicole L.A. Catherine PhD, Michael Boyle PhD, Yufei Zheng MPH, Lawrence McCandless PhD, Hui Xie PhD, Rosemary Lever MA, Debbie Sheehan MSW, Andrea Gonzalez PhD, Susan M. Jack RN PhD, Amiram Gafni PhD, Lil Tonmyr PhD, Lenora Marcellus RN PhD, Colleen Varcoe RN PhD, Ange Cullen MPH, Kathleen Hjertraas BSc, Caitlin Riebe BSc, Nikolina Rikert BA, Ashvini Sunthoram BSc, Ronald Barr MDCM, Harriet MacMillan MD, Charlotte Waddell MD

Abstract

Background: Nurse-Family Partnership (NFP) involves public health nurses providing frequent home visits from early pregnancy until children reach age 2 years, focusing on first-time parents experiencing socioeconomic disadvantage. Our aim was to evaluate NFP's effectiveness in improving child and maternal health.

Methods: We conducted an analysis of prenatal secondary outcomes in an ongoing randomized controlled trial in British Columbia; the data used in this analysis were collected from January 2014 to May 2017. Participants were pregnant girls and women aged 14-24 years who were preparing to parent for the first time and experiencing socioeconomic disadvantage. They were randomly allocated 1:1 to the intervention (NFP plus existing services) or control group (existing services). Prespecified prenatal secondary outcome indicators were changes in use of nicotine cigarettes and alcohol use by 34-36-weeks' gestation. We also report on prespecified exploratory cannabis and street drug use measures. We used mixed-effect models for longitudinal and clustered data to estimate intervention effects. Analyses were by intention to treat.

Results: The median gestational age at baseline for the 739 participants (368 participants in the intervention group, 371 in the comparison group) was 20 weeks, 6 days. By 34-36-weeks' gestation, NFP significantly reduced cigarette counts (over the past 2 d) (difference in changes [DIC] of count -1.6, 95% confidence interval [CI] -6.4 to -1.3) in those who smoked. NFP also significantly reduced rates of prenatal cannabis use (DIC -0.4, 95% CI -17.0 to -1.7), but not rates of street drug or "any" substance use. While we observed decreased rates of cigarette and alcohol use in both groups (DIC of proportions -2.8, 95% CI -15.3 to 0.6; DIC -0.5, 95% CI -8.7 to 1.8, respectively), these changes were not statistically significant.

Interpretation: We found no evidence that NFP was effective in reducing rates of prenatal cigarette and alcohol use; however, it led to reduced prenatal cannabis use, and in smokers it led to modest reductions in cigarette use. NFP may therefore hold promise for reducing some types of prenatal substance use in disadvantaged populations. **Trial registration:** ClinicalTrials.gov, no. NCT01672066.
